Decoder

- A decoder is a combinational circuit that converts binary information from n input lines to m (maximum of 2^n) unique output lines
  - n-to-m-line decoder
- A binary one-hot decoder converts a symbol from binary code to a one-hot code
  - Output variables are mutually exclusive because only one output can be equal to 1 at any time (the 1-minterm)
- Example
  - binary input a to one-hot output b
  - b[i] = 1 if a = i or b= 1<< a
  - a stands for position of 1 in b

Step 4

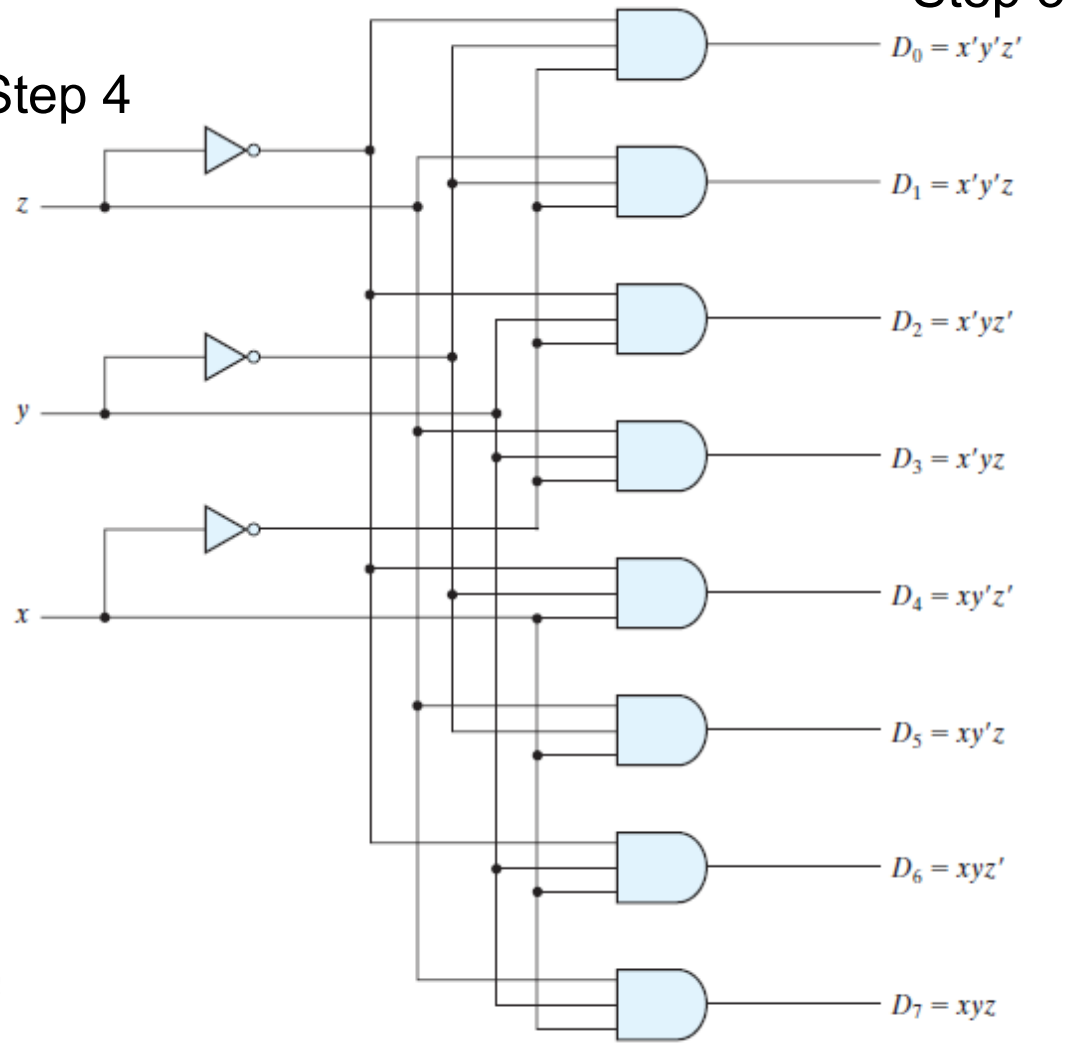
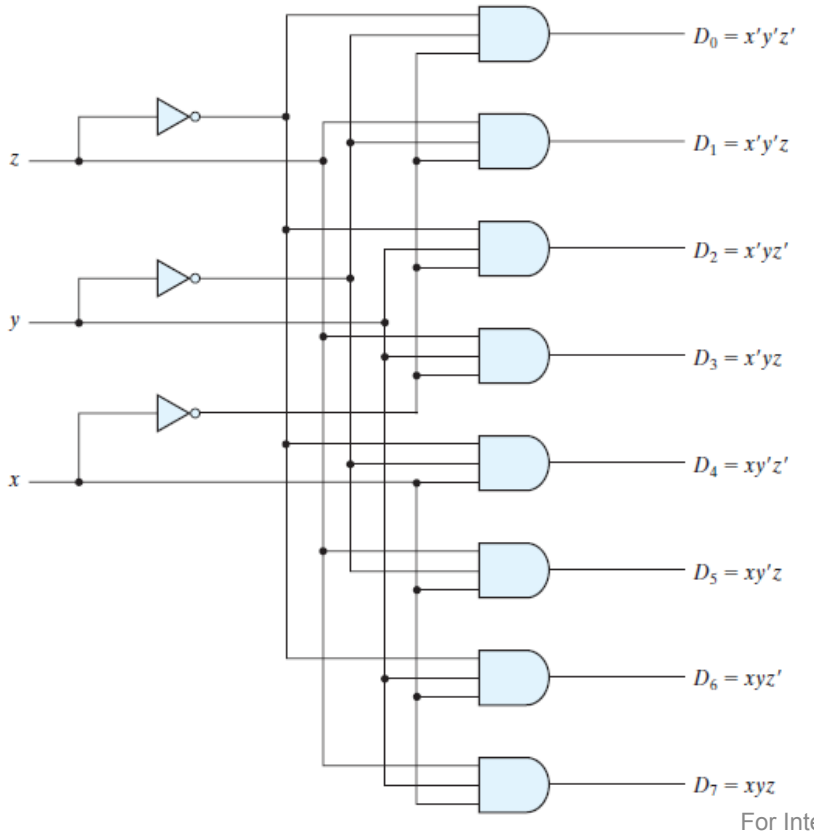
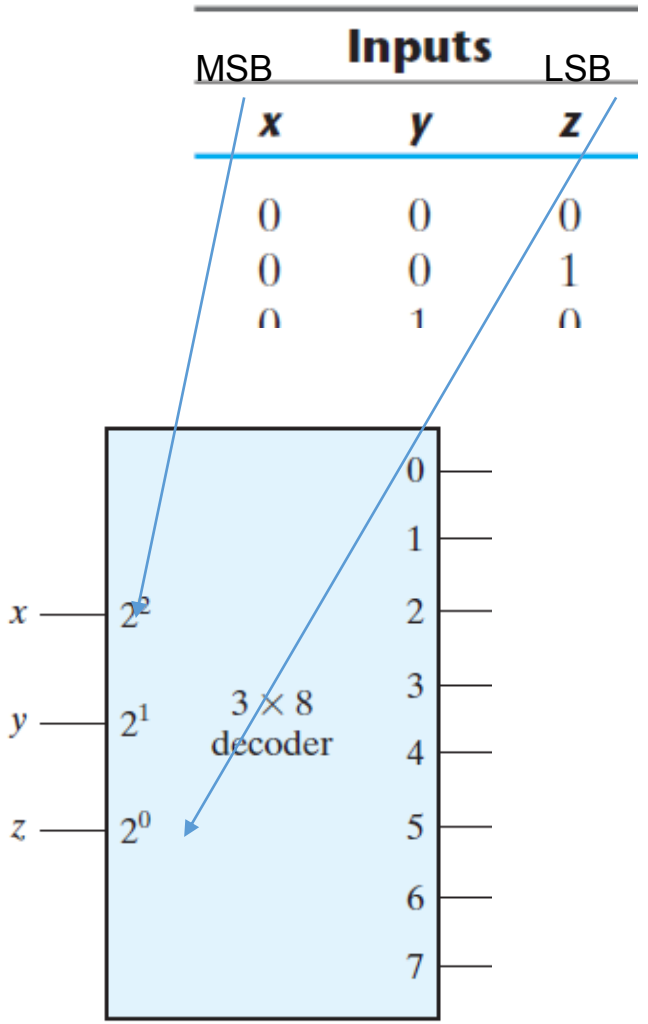


Graphic Symbol of Decoder

- We can use graphic symbol/block diagram
  - You must clearly denoting the input and output within decoder's box





Main Usages of Decoders

- Minterm generator:
  - Generate the 2^n (or fewer) minterms of n input variables. For example: a 3-8 line decoder
- Data demultiplexing:
  - A decoder with enable input can function as a demultiplexer – a circuit that receives information from a single line and directs it to one of 2^n possible output lines.
- Display decoding:
  - Decoders are used in display systems to select a specific output line based on the input code and drive the corresponding segment of the display.
- Address decoding:
  - Identify a memory cell, disk sector, or other memory or storage device, to ensure one device can communicate with the processor at one time.

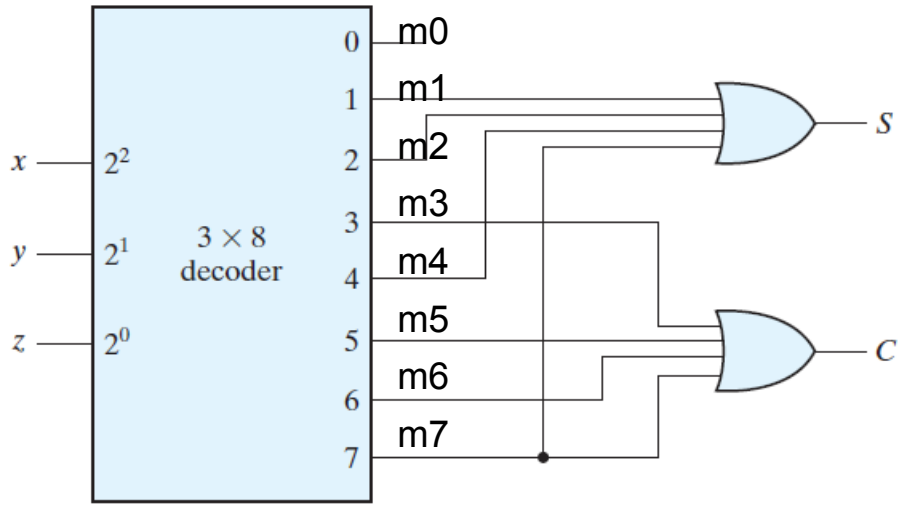
Decoder for logic implementation Example1

- Decoder can be used to implement the logic function by connecting the appropriate minterms to an OR gate.
  - Any combinational circuit with n inputs and m outputs can be implemented with an n-to-2^n decoder in conjunction with m external OR gates

x	y	z	C	S
0	0	0	0	0
0	0	1	0	1
0	1	0	0	1
0	1	1	1	0
1	0	0	0	1
1	0	1	1	0
1	1	0	1	0
1	1	1	1	1

$S(x, y, z) = \sum(1, 2, 4, 7)$

$C(x, y, z) = \sum(3, 5, 6, 7)$



Decoder for logic implementation Example2

- Exercise:
  - Implement Y = A XNOR B using a 2-to-4 line decoder and external OR gate, you need to clearly write down the input and output pins

Y = A XNOR B
= (A ⊕ B)'
= A'B' + AB
= ∑(0, 3)
Connect output 0 and 3 to an OR gate

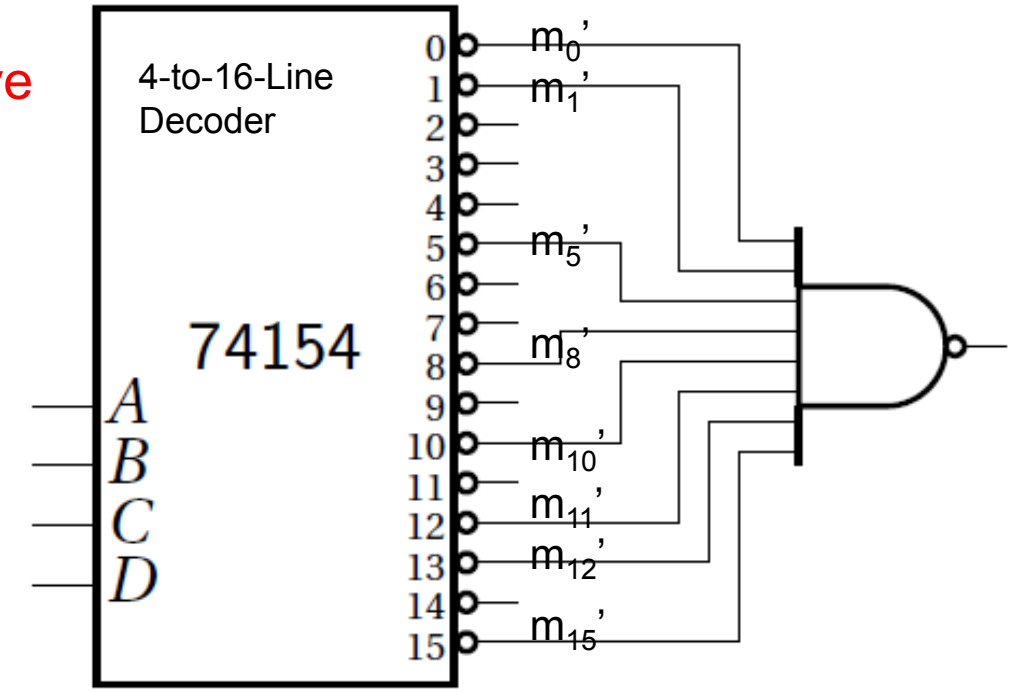
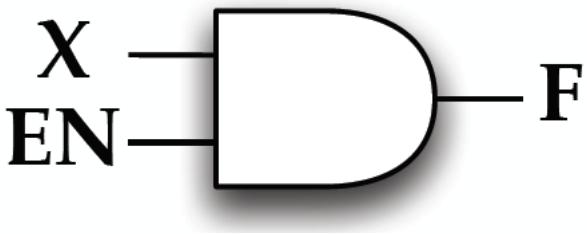
Decoder for logic implementation Example3

- Using 74154 for logic function implementation
  - 74154: a 4-to-16 line decoder
  - Characteristics: If A = B = C =D= 0 the output 0 of the decoder is 0 while all other outputs are 1.(active low output) → generate inverse of minterms
- Example:
  - F(A,B,C,D) = ∑(0, 1, 5, 8,10,12,13,15).
    = $[(m_0+m_1+m_5+m_8+m_{10}+m_{12}+m_{13}+m_{15})']'$
    $=(m_0' \cdot m_1' \cdot m_5' \cdot m_8' \cdot m_{10}' \cdot m_{12}' \cdot m_{13}' \cdot m_{15}')'$
  - thus a nand gate is used instead of an or gate



Enabling

- Enabling permits an input signal to pass through to an output.



- F = EN•X

EN	X	F
0	0	0
0	1	0
1	0	0
1	1	1

高电平有效使能：EN=1 有效

低 ～ EN=0 有效

$Y = S'I_0 + SI_1$

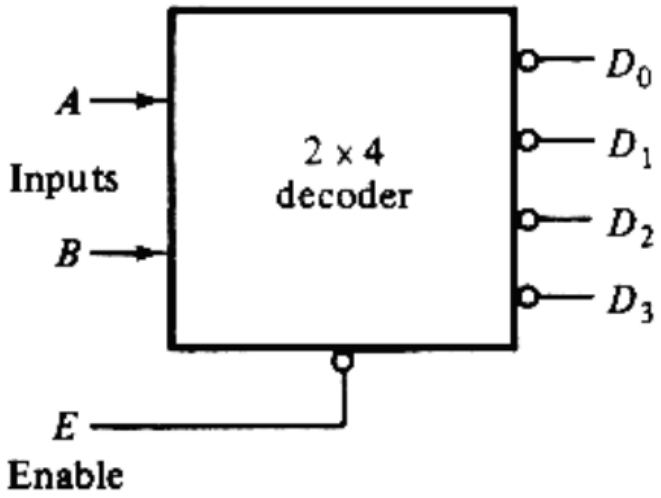
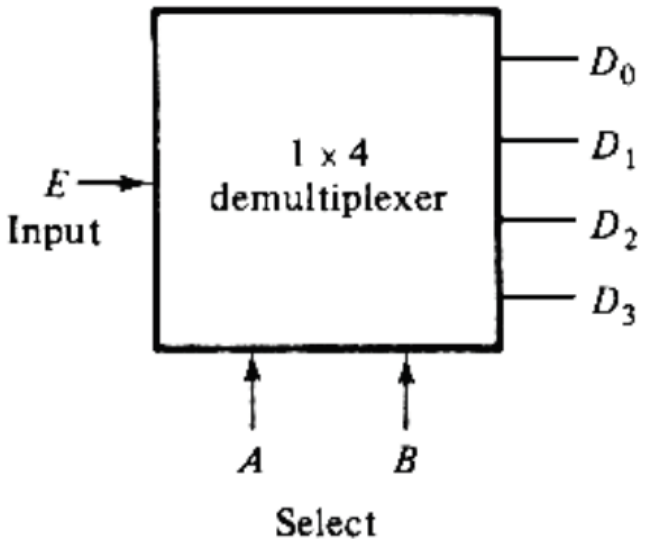
Demultiplexer

- A decoder with enable input can function as demultiplexer
  - a circuit that receives information from a single line and directs it to one of 2^n possible output lines.
  - Because decoder and demultiplexer operations are obtained from the same circuit, a decoder with an enable input is referred to as a demultiplexer.





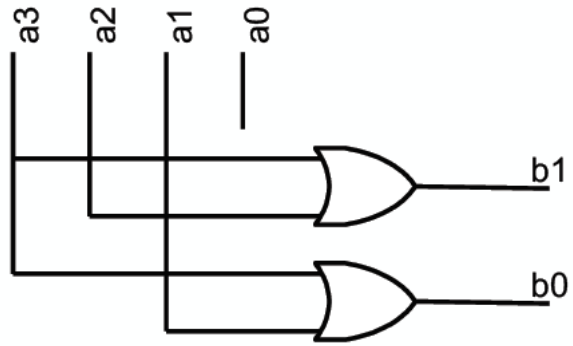
Outline

- Decoder
- Multiplexer
- **Encoder**

Encoder

- An encoder is an inverse of a decoder
- Encoder is a logic module that converts a one-hot input signal to a binary-encoded output signal
- Other input patterns are **forbidden** in the truth table
- Example: a 4->2 encoder

a_3	a_2	a_1	a_0	b_1	b_0
0	0	0	1	0	0
0	0	1	0	0	1
0	1	0	0	1	0
1	0	0	0	1	1



$b_0 = a_3 + a_1$

$b_1 = a_3 + a_2$

Encoder

- A combinational logic that performs the inverse operation of a decoder
  - Only one input has value 1 at any given time
  - Can be implemented with OR gates
- However, when both D3 and D6 goes 1, the output will be 111 (ambiguity)!

- Assuming D_3 has the highest priority, while D_0 has the lowest priority.
- X is the don't care conditions, V is the valid output indicator.
